Q02 Understanding Check

Question. A model crosses 50% accuracy on a benchmark only after it reaches a certain scale. Name two different explanations for this apparent threshold and one experiment that could help distinguish them.

Expected answer. A new/useful computation may become available, or a smooth improvement may cross a thresholded metric/prompt-sensitive boundary. Replot a continuous metric, vary task thresholds and prompts, or test another model family/held-out distribution.

Diagnoses the misconception that a sharp-looking score curve alone establishes a new internal ability.
