Q12 Discussion Questions

1. If parametric accuracy is frequency-dependent, what does that imply about whose knowledge an LLM encodes — and is "the long tail" a technical limitation or a mirror of the corpus? Defend a position.
2. The cutoff asymmetry (skills persist, facts don't) suggests facts and skills are stored differently. What evidence from Q13 (probing, editing) supports or complicates that separation?
3. Adaptive retrieval — retrieve only for rare entities — matches always-retrieving at a fraction of the cost. What failure modes could an *estimate* of entity rarity itself introduce?
4. Kadavath et al. find better-than-expected calibration on multiple-choice probes, yet models still answer unanswerable open-ended questions. What gets lost between "representing uncertainty" and "acting on it"?
5. Fine-tuning on new knowledge increases hallucination. Given that, how would you design a course assistant for a field with post-cutoff developments? Which of the boundary map's mechanisms would you rely on?
