Q18: Comprehension Check

DLS 2026 — Kukla

October 2026

Comprehension check. A researcher shows that a language model solves a reasoning task with the same accuracy and error pattern as humans, and concludes "the model thinks like a brain." Name the specific inference error, and state what *additional* kind of evidence would be needed to support a claim of mechanistic similarity.

Answer. The error is inferring *mechanistic* similarity from *behavioral* similarity—matching outputs (and even error patterns) does not show the internal process is the same. Supporting mechanistic similarity would require evidence about the computation itself: e.g. that the model's internal representations predict neural activity during the same task, that identified circuits correspond to known neural processes, or that causal interventions (ablation/patching) produce effects analogous to lesion/stimulation studies in brains. Representational and causal-mechanistic evidence, not behavioral matching, is what the claim needs.
