Q25: Discussion Questions

DLS 2026 — Kukla

October 2026

1. Distillation lets a small student learn from a large teacher. What does the student gain, what can it never gain, and why is this not "free" capability?
2. RLAIF replaces human preference labels with model-generated ones. Under what conditions does that preserve alignment quality, and when does it quietly degrade it?
3. LLM-as-judge is biased toward its own style and longer answers. Design an evaluation protocol that uses AI judging at scale while controlling these biases.
4. Model collapse happens when models train on recursively generated data. What minimum amount or kind of fresh human data do you think is needed to prevent it, and how would you test that?
5. If an agent can propose and run its own ML experiments, what is the single most important human-held checkpoint you would keep in that loop, and why?
